Methoden moderner Röntgenphysik: Streuung und Abbildung

Lecture 6	Vorlesung zum Haupt- oder Masterstudiengang Physik, SoSe 2019
	G. Grübel, L. Müller, O. Seeck, L. Frenzel, F. Lehmkühler, M. Martins, W. Wurth
Location	Lecture hall AP, Physics, Jungiusstraße
Date	Tuesdays 12:30 - 14:00 (starting 2.4.)
	Thursdays 8:30 - 10:00 (until 11.7.)

Methoden moderner Röntgenphysik: Streuung und Abbildung

Part I:
Basics of X-ray Physics
by Gerhard Grübel (GG)

Introduction
Overview, Introduction to X-ray Scattering

X-ray Scattering Primer
Elements of X-ray Scattering

Sources of X-rays, Synchrotron Radiation
Laboratory Sources, Accelerator Bases Sources

Reflection and Refraction from Interfaces
Snell's Law, Fresnel Equations

Kinematical Diffraction (I)
Diffraction from an Atom, a Molecule, from Liquids, Glasses, …

Kinematical Diffraction (II)
Diffraction from a Crystal, Reciprocal Lattice, Structure Factor, …

# Scattering from a Crystal

$$A(\mathbf{Q}) = -r_0 \sum_{r_{j'}} e^{i\mathbf{Q}r_{j'}}$$

An extension to crystalline matter is simplified since there is translational symmetry.

Crystalline matter: $\mathbf{r}_j' = \mathbf{R}_n + \mathbf{r}_j$

$$A(\mathbf{Q}) = -r_0 \underbrace{\sum_{R_n} e^{i\mathbf{Q}\mathbf{R}_n}}_{\text{lattice sum}} \underbrace{\sum_{r_j} e^{i\mathbf{Q}\mathbf{r}_j}}_{\text{unit cell structure factor}}$$

Crystallography:

Determine electron density within unit cell

Note: one does measure
$I(Q) = A(Q) A^*(Q)$
and is thus not sensitive to phase shifts

Methoden Moderner Röntgenphysik - Vorlesung im Haupt-/Masterstudiengang, Universität Hamburg, SoSe 2019, G. Grübel

Scattering from Atoms on a Crystal Lattice

Concept: build up crystal from **lattice** + **basis**

2-D lattice: $\mathbf{R}_n = n_1\mathbf{a}_1 + n_2\mathbf{a}_2$

<u>Unit cell:</u> primitive or (non-) primitive
 (primitive ≡ area or volume minimized)

3-D lattice: $\mathbf{R}_n = n_1\mathbf{a}_1 + n_2\mathbf{a}_2 + n_3\mathbf{a}_3$

There are: 5 distinct lattices in 2-D

   14 distinct lattices in 3-D

called the Bravais lattices

Add basis to yield:

          32   possible point groups
          230   possible symmetry groups

(a) primitive   (b) non-primitive

(c) non-conventional

(d) Crystal=lattice+basis

Lattice   Basis   Crystal

Lattice Planes and Miller Indices

The plane closest to the origin that has intercepts a_1/h, a_2/k, a_3/l is called the (h,k,l) plane

Rhombohedral, $a = b = c$, $\alpha = \beta = \gamma$:

$$\frac{1}{d_{hkl}^2} = \frac{(h^2 + k^2 + l^2)\sin^2\alpha + 2(hk + kl + lh)(\cos^2\alpha - \cos\alpha)}{a^2(1 + 2\cos^3\alpha - 3\cos^2\alpha)}.$$

Hexagonal, $a = b$, $\alpha = \beta = 90°$, $\gamma = 120°$:

$$\frac{1}{d_{hkl}^2} = \frac{4}{3}\left(\frac{h^2 + hk + k^2}{a^2}\right) + \frac{l^2}{c^2}.$$

Monoclinic, $\alpha = \gamma = 90°$:

$$\frac{1}{d_{hkl}^2} = \frac{1}{\sin^2\beta}\left(\frac{h^2}{a^2} + \frac{k^2\sin^2\beta}{b^2} + \frac{l^2}{c^2} - \frac{2hl\cos\beta}{ac}\right).$$

Orthorhombic, $\alpha = \beta = \gamma = 90°$:

$$\frac{1}{d_{hkl}^2} = \frac{h^2}{a^2} + \frac{k^2}{b^2} + \frac{l^2}{c^2}.$$

Tetragonal, $a = b$, $\alpha = \beta = \gamma = 90°$:

$$\frac{1}{d_{hkl}^2} = \frac{h^2 + k^2}{a^2} + \frac{l^2}{c^2}.$$

Cubic, $a = b = c$, $\alpha = \beta = \gamma = 90°$:

$$\frac{1}{d_{hkl}^2} = \frac{h^2 + k^2 + l^2}{a^2}.$$

spacing formulae; B.E. Warren p.21

Laue Conditions and Reciprocal Space

Position of an atom in lattice and cell:

$$\mathbf{R_n} + \mathbf{r_j}$$

origin unit cell   atom in cell

$$F^{crystal}(\mathbf{Q}) = \sum_{\mathbf{r_j}} F_j{}^{mol}(\mathbf{Q}) e^{i\mathbf{Q}\mathbf{r_j}} \bullet \sum_{\mathbf{R_n}} e^{i\mathbf{Q}\mathbf{R_n}}$$

unit cell structure factor   lattice sum

Evaluation of the Lattice Sum:

$$\sum_{\mathbf{R}_n} e^{i\mathbf{Q}\mathbf{R}_n} \qquad (i)$$

number of terms is enormous

(i) is of order unity (many $e^{i\phi}$ terms) except for:

$$\mathbf{Q}\bullet\mathbf{R}_n = 2\pi \times \text{integer} \qquad (ii)$$

in that case the lattice sum becomes big.

Concept: construct an artificial lattice with lattice vectors $\mathbf{a}_1{}^*$, $\mathbf{a}_2{}^*$ and $\mathbf{a}_3{}^*$ such that:

$$a_i \bullet a_j{}^* = 2\pi \, \delta_{ij} \qquad (iia)$$

then any vector defined on the **reciprocal lattice** is of type:

$$\mathbf{G} = h\mathbf{a}_1{}^* + k\mathbf{a}_2{}^* + l\mathbf{a}_3{}^* \qquad (iii)$$

(iii): **G** satisfies (ii) [$\mathbf{Q}\bullet\mathbf{R}_n \times \text{integer}$]

since

$$\mathbf{G}\bullet\mathbf{R}_n = 2\pi \,(hn_1 + kn_2 + ln_3)$$

only if

$$\mathbf{Q} = \mathbf{G} \qquad (\textbf{Laue condition})$$

so that the scattering amplitude will not vanish.

Thus: Q needs to be a reciprocal lattice vector.

Laue condition

Q = G

Wave vector transfer has to be a reciprocal lattice vector

Reciprocal Lattice

1-D: defined by (iia): $a_i \bullet a_j^* = 2\pi \, \delta_{ij}$

2-D and 3-D:

$$a_1^* = \frac{2\pi}{v_c} a_2 \times a_3$$

$$a_2^* = \frac{2\pi}{v_c} a_3 \times a_1$$

$$a_3^* = \frac{2\pi}{v_c} a_1 \times a_2$$

with $v_c = a_1 \bullet (a_2 \times a_3)$

Note: in 2-D a_3 is chosen to be a unit vector normal to the 2-D plane spanned by a_1 and a_2.

Example: fcc lattice

$$a_1 = \left(\frac{a}{2}\right)(y' + z'), \qquad a_2 = \left(\frac{a}{2}\right)(z' + x'),$$

$$a_3 = \left(\frac{a}{2}\right)(x' + y')$$

$$a_1^* = \frac{4\pi}{a}\left(\frac{y'}{2} + \frac{z'}{2} - \frac{x'}{2}\right)$$

$$a_2^* = \frac{4\pi}{a}\left(\frac{z'}{2} + \frac{x'}{2} - \frac{y'}{2}\right)$$

$$a_3^* = \frac{4\pi}{a}\left(\frac{x'}{2} + \frac{z'}{2} - \frac{y'}{2}\right)$$

(x', y', z' unit vectors)

Real   Reciprocal

1D, 2D, 3D (fcc, bcc)
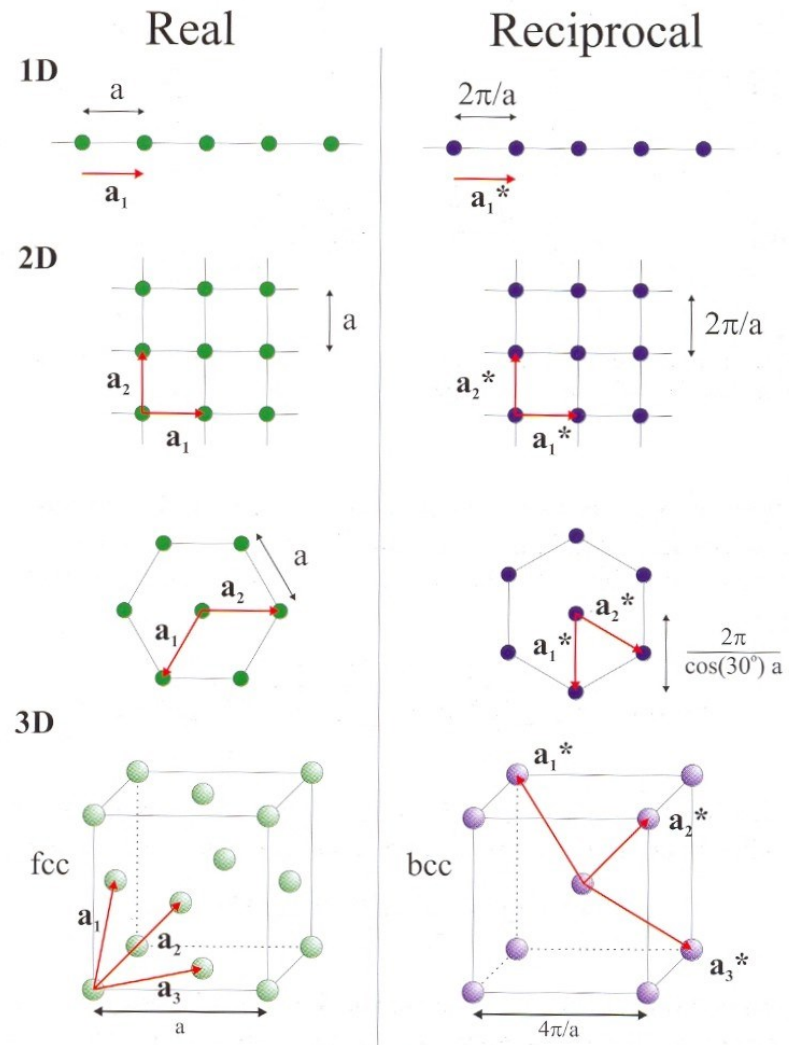

Equivalence of the Laue and the Bragg Conditions

(a) Equivalence of Bragg and Laue

Bragg: $\lambda = 2d\sin\theta$

Laue: $Q = G$

Real — Reciprocal

(b) Miller indices and reciprocal lattice vectors
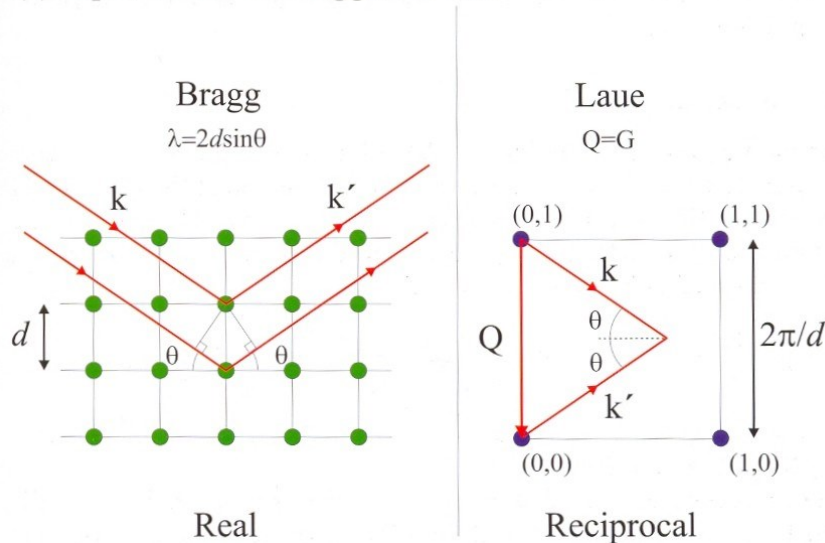

<u>Bragg's law:</u> $\sin\theta = \dfrac{\lambda}{2d}$

The Laue condition requires
$$\mathbf{Q} = \mathbf{G}$$

<u>Example</u>:
$$\mathbf{Q} = (0,1) = 0 \bullet \mathbf{a}_1^* + 1 \bullet \mathbf{a}_2^*$$

$$= \frac{2\pi}{d}\mathbf{x_2}'$$
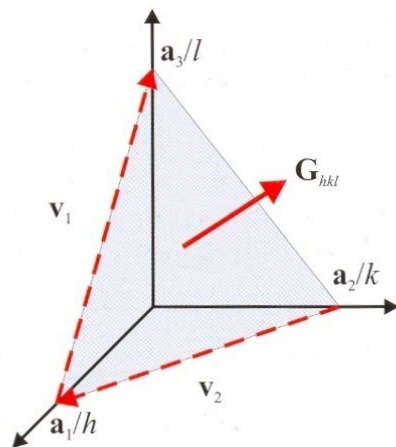

$$\sin\theta = \frac{\left(\dfrac{Q}{2}\right)}{k} = \frac{Q\lambda}{4\pi}$$

$$\sin\theta = \frac{\dfrac{2\pi}{d}\lambda}{4\pi} = \frac{\lambda}{2d} \quad \mathrm{q.\,e.\,d.}$$

The Ewald Sphere

Visualization of diffraction effects in reciprocal space (a).

Laue condition requires $\mathbf{Q} = \mathbf{G} = h\mathbf{a}_1^* + k\mathbf{a}_2^*$

Design sphere with radius k pointing to origin (b).

If any reciprocal lattice point falls on the circle then the Laue conditions is fulfilled (c).

Intensity is observed if the detector is placed in the direction of k' (c).

A rotation about O corresponds to a rotation of the crystal.

Note: More than one reciprocal lattice point can lie on the sphere ≡ multiple scattering.

If the beam is not monochromatic the sphere adopts the corresponding width. In the white beam case all spots are ultimately detected.
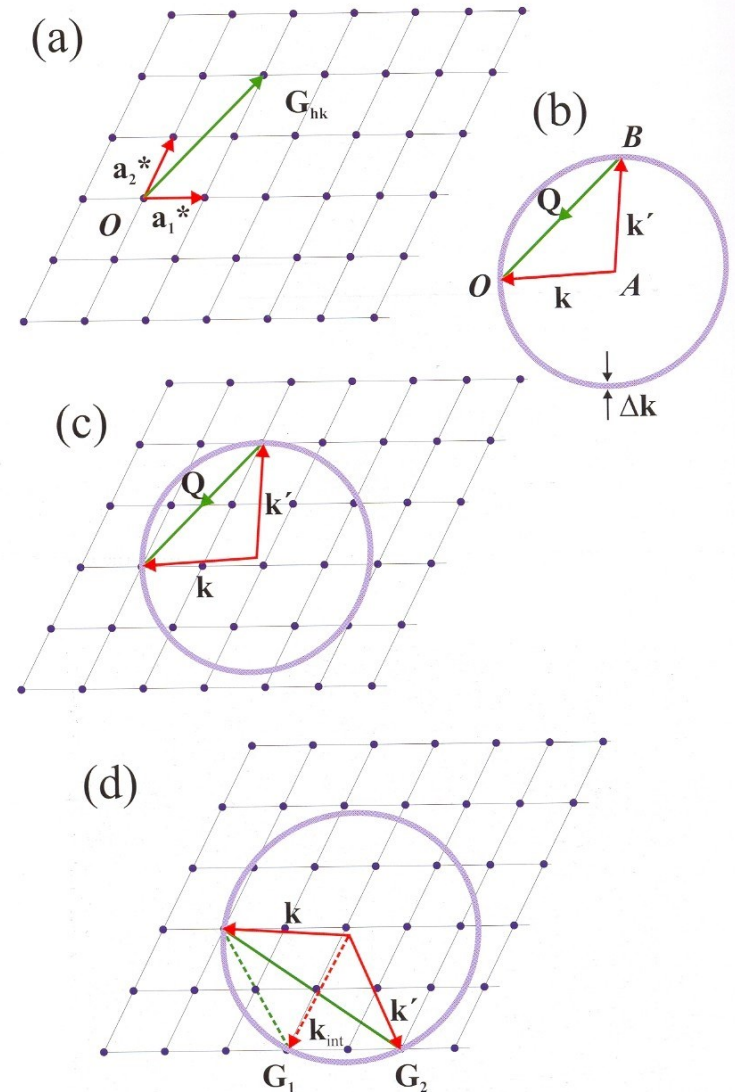

The Unit Cell Structure Factor

$$F^{uc}(\mathbf{Q}) = \sum_{rj} F_j^{mol}(\mathbf{Q}) e^{i\mathbf{Q}\mathbf{r_j}}$$

<u>Example:</u> fcc lattice *(use conventional cubic unit cell)*

$$\mathbf{r}_1 = \mathbf{0} \quad, \quad \mathbf{r}_2 = \frac{1}{2}a\left(\underline{y}+\underline{z}\right) \quad, \quad \mathbf{r}_3 = \frac{1}{2}a(\underline{z}+\underline{x}) \quad, \quad \mathbf{r}_4 = \frac{1}{2}a\left(\underline{x}+\underline{y}\right)$$

$$\mathbf{G} = h\mathbf{a}_1^* + k\mathbf{a}_2^* + l\mathbf{a}_3^*$$

$$\mathbf{a}_1^* = \frac{2\pi}{v_c}(\mathbf{a_2}\times\mathbf{a}_3) = \frac{2\pi}{a^3}\left[a\underline{y}\times a\underline{z}\right] = \frac{2\pi}{a}\left[\underline{y}\times\underline{z}\right] = \frac{2\pi}{a}\underline{x}$$

$$\mathbf{a}_2^* = \frac{2\pi}{v_c}(\mathbf{a_2}\times\mathbf{a}_3) = \frac{2\pi}{a^3}\left[a\underline{z}\times a\underline{x}\right] = \frac{2\pi}{a}\left[\underline{z}\times\underline{x}\right] = \frac{2\pi}{a}\underline{y}$$

$$\mathbf{a}_3^* = \frac{2\pi}{v_c}(\mathbf{a_2}\times\mathbf{a}_3) = \frac{2\pi}{a^3}\left[a\underline{x}\times a\underline{y}\right] = \frac{2\pi}{a}\left[\underline{x}\times\underline{y}\right] = \frac{2\pi}{a}\underline{z}$$
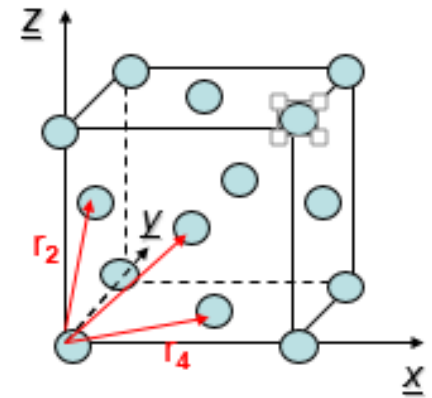

$$v_c = \mathbf{a}_1\bullet(\mathbf{a}_2\times\mathbf{a}_3)$$

$$\mathbf{G}\bullet\mathbf{r}_1 = \frac{2\pi}{a}\left(h\underline{x}+k\underline{y}+l\underline{z}\right)\bullet\mathbf{0} \qquad\qquad = 0$$

$$\mathbf{G}\bullet\mathbf{r}_2 = \frac{2\pi}{a}\left(h\underline{x}+k\underline{y}+l\underline{z}\right)\bullet\frac{1}{2a}\left(\underline{y}\times\underline{z}\right) \quad = \pi(k+l)$$

$$\mathbf{G}\bullet\mathbf{r}_3 = \frac{2\pi}{a}\left(h\underline{x}+k\underline{y}+l\underline{z}\right)\bullet\frac{1}{2a}\left(\underline{z}\times\underline{x}\right) \quad = \pi(h+l)$$

$$\mathbf{G}\bullet\mathbf{r}_4 = \frac{2\pi}{a}\left(h\underline{x}+k\underline{y}+l\underline{z}\right)\bullet\frac{1}{2a}\left(\underline{x}\times\underline{y}\right) \quad = \pi(h+k)$$

"Thermal Diffuse Scattering" (TDS)

$$f^{atom} = f(Q) e^{-\frac{1}{2}Q^2 <u^2>} = f(Q) e^{-M}$$

with e^{-M} : Debye-Waller factor
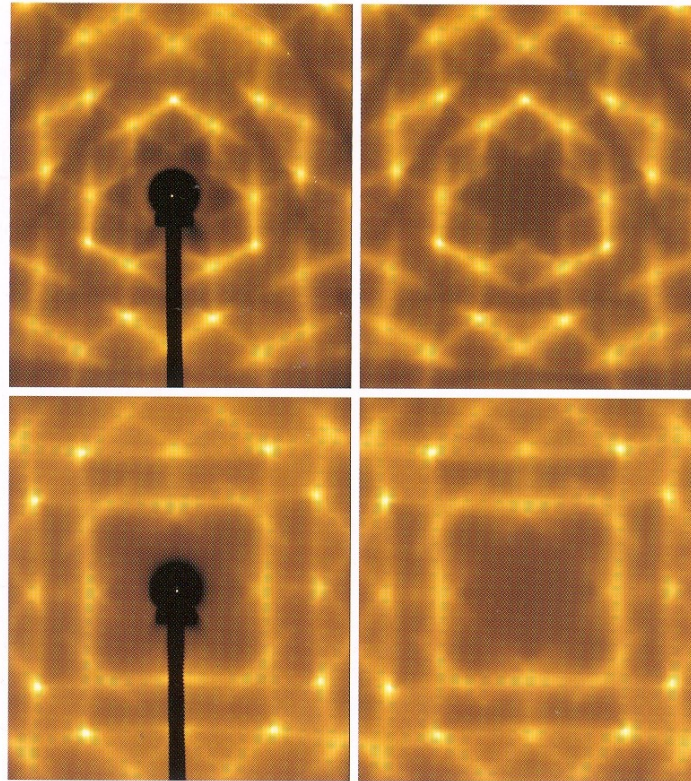

Thermal Diffuse Scattering (TDS)

Figure 4.18: Thermal diffuse scattering (TDS) from Si. The data were collected in a transmission geometry (photon energy 28 keV) using an image plate detector. The data were collected on the UNI-CAT beamline at the Advanced Photon Source in an exposure time of ~10 s. The top and bottom left panels show the data taken with a (111) and a (100) axis parallel to the incident beam respectively. The data are plotted on a logarithmic scale. The brighter spots are not Bragg peaks, as the Laue condition is never exactly fulfilled, but are due to the build up of TDS close to the position of where the Bragg peaks would occur. The right panels show the corresponding calculated images based on a simultaneous pixel-by-pixel fit to the data [Holt et al., 1999].

Debye-Waller Factor (DWF)

Unit cell structure factor including the DWF

$$F^{\text{unit cell}} = \sum_j f_j(Q) e^{-M_j} e^{i\mathbf{Q}\bullet r_j}$$

$$B_T = \frac{6h^2}{m_A k_B \Theta} \left\{ \left(\frac{\phi(\Theta/T)}{\Theta/T} \right) + \frac{1}{4} \right\}$$

$$M_j = \frac{1}{2} Q^2 <u_j^2> = \frac{1}{2} \left(\frac{4\pi}{\lambda} \right)^2 (\sin\theta)^2 <u_j^2>$$

$$= B_j^T \left(\frac{\sin\theta}{\lambda} \right)^2$$

with $B_j^T = 8\pi^2 <u_j^2>$

With $\phi(x) \equiv \left(\frac{1}{x}\right) \int_0^x \frac{\xi}{(e^\xi - 1)} \, d\xi$

Θ: Debye temperature

m_A: atomic mass

For isotropic vibrations:

$$<u^2> = <u_x^2 + u_y^2 + u_z^2> = 3 <u_c^2>$$

$$B_{T, \text{isotropic}} = \frac{8\pi^2}{3} <u_j^2>$$

$$B_T[\text{Å}^2] = \frac{11492 T[K]}{A\Theta^2[K^2]} \phi(\Theta/T) + \frac{2873}{A\Theta[K]}$$

Debye-Waller Factor

$$B_T[\text{Å}^2] = \left\{ \frac{11492T[K]}{A\Theta^2[K^2]} \right\} \Phi(\Theta/T) + \frac{2873}{A\Theta[K]}$$
